Using cURL

Once you have signed up for Amazon Associates program and Creators API, you can start sending requests to the API. You can send requests to Creators API using SDKs (recommended) or directly using HTTP requests. This guide shows you how to make API calls using cURL.

Request Components

Requests to Creators API have the following main components:

1. **Headers** - Authentication and metadata about the request
2. **Request Payload** - JSON formatted Request Body

The following sections explain how to obtain the authentication token for headers, how to construct the request payload, and finally how to put everything together in a complete cURL command.

Step 1: Fetch Access Token (for Headers)

To authenticate your requests, you need to obtain an OAuth 2.0 access token from the Cognito token endpoint. This token will be used in the Authorization header for all API calls.

Regional Endpoints

The Creators API uses different authentication endpoints based on your credential version:

Region	Version	Token Endpoint	Marketplaces
NA (North America)		creatorsapi-auth.us-east-1
